# Work report ForestBIOTA: <br> Assessment and evaluation of stand structure data 

April 2006<br>P. Meyer<br>Northwest-German Forestry Research Station

## 1 Introduction

The ForestBIOTA project aims at the further development of biodiversity monitoring activities specifically at Level II plots of the EU and ICP Forests monitoring programme. Recommendations shall be given for an optimized
a) indicator system of forest biodiversity and
b) a suitable methodology for the assessment of biodiversity at Level II plots in European forests.
This will facilitate recommendations for assessment methods applicable within different surveys (e.g. Intensive Monitoring, Level I, National Forest Inventories).

In a test-phase assessments of forest biodiversity in different fields of interest have been carried out in 11 European countries taking part in ForestBIOTA. As key attributes of forest biodiversity dead wood, epiphytic lichens, ground vegetation, forest classification and stand structure were selected. Results were submitted to the PCC (BFH, Hamburg) which checked data quality and created a database. Afterwards experts evaluated the gathered data. In a final step correlative studies were carried out in order to detect relationships between indices within and/or between fields of interest.

The presented work report summarizes the methodology of field assessment and data analysis concerning stand structure within ForestBIOTA.

## 2 Selected indices and simple estimates

The ForestBIOTA partners agreed on a list of stand structural indices to be computed by the experts and a methodology for the assessment of stand structure and dead wood, which is layed down in Anonymus (2004) based on Fischer and Pommerening (2003), Chirici et al. (2003) and Meyer (2004). Following, the agreements on indices are described and contrasted with the delivered data.

## Approach

Different indices characterizing stand structure shall be tested. Suitable indices shall reveal valid results and react sensitive to structural differences between sites and stands as well as structural dynamics. Furthermore it is advantageous if necessary data can efficientely be assessed and computation is simple. The parameters can be divided into two groups: spatially explicit indices and indices without spatial relationships (s. Tab. 1).

Tab. 1: List of selected structural indices

| Name | Formula | Short description | Source |
| :---: | :---: | :---: | :---: |
| Spatially explicit indices |  |  |  |
| Clark Evans Index | $\begin{aligned} & C E=\frac{\frac{1}{n} \sum_{i=1}^{n} r_{i}}{0,5 \sqrt{10000 / N}} \\ & \begin{array}{l} \text { with } \\ r_{i}=\text { distance of tree }{ }_{i} \text { to next neighbour } \\ \mathrm{N}=\text { number of trees per ha } \\ \mathrm{n}=\text { number of sample trees } \end{array} \\ & \hline \end{aligned}$ | measure for regular or clustered horizontal distribution | Clark and Evans 1954 |
| Contagion Index | $\begin{aligned} & W_{i}=\frac{1}{4} \sum_{1}^{4} W_{j} \\ & \begin{array}{l} \text { with } \\ w_{i}=1 \text { if } \alpha \text { angle } j<90^{\circ} \\ w_{i}=0 \text { otherwise } \end{array} \end{aligned}$ | defines the degree of regularity of the distribution of tree positions | Gadow et al. 1998 |
| Mingling Index | $M I_{i}=\frac{1}{4} \sum_{j=1}^{4} v_{i j}$ <br> with <br> $\mathrm{v}_{\mathrm{ij}}=0$ in case that neighbour ${ }_{j}$ belongs to same species and <br> $\mathrm{v}_{\mathrm{ij}}=1$ in case that neighbour ${ }_{j}$ belongs to same species | describes the probability that none of the three nearest trees belongs to the tree species of the centre tree | Gadow and Füldner 1995 |
| Diameter differentiation | $\begin{aligned} & T=\frac{1}{n} \sum_{i=1}^{n}\left(1-r_{i}\right) \\ & \text { with } \\ & r_{i}=\text { (thinner dbh)/(thicker dbh) of tree pair }{ }_{i} \\ & n=\text { number of measured tree pairs } \end{aligned}$ | Quantifies the degree of diameter differentiation | Gadow and Füldner 1995 |
| Indices without spatial relation |  |  |  |
| Shannon Index of diversity | $\begin{aligned} & H^{\prime}=-\sum_{i}^{N} \log p_{i} \cdot p_{i} \\ & \text { with } \\ & p_{i}=\text { relative abundance of the ith species } \\ & \mathrm{N}=\text { number of species (log }=\text { natural logarithm } \\ & (\text { base }=\text { e }) \text { ) } \end{aligned}$ | ecological standard measure for diversity | Shannon 1948 |
| Evenness | $\begin{aligned} & E=\frac{H^{\prime}}{H^{\prime}} \\ & \text { with } \\ & H^{\prime}=\text { Shannon-Index } \\ & H^{\prime} \text { 'axa }=\text { Potential maximum value }(=\log \mathrm{N} \\ & \text { [species number]) } \end{aligned}$ | ecological standard measure for diversity | Pielou (1975) |
| Simpson index of diversity | $\begin{aligned} & S I=\sum_{i}^{N}\left(1-p_{i}\right) \cdot p_{i} \\ & \text { with } \\ & p_{i}=\text { relative abundance of the ith species } \\ & N=\text { number of species } \end{aligned}$ | ecological standard measure for diversity | Simpson 1949 |
| Species profile index | $A=-\sum_{i=1}^{S} \sum_{j=1}^{B} \log \left(p_{i j}\right) \cdot p_{i j}$ <br> with <br> $\mathrm{p}_{\mathrm{ij}}=$ proportion of species i in height band j <br> $\mathrm{S}=$ number of different tree species <br> $B=$ number of height bands <br> band 1: 100-80\% of maximal tree height $\left(\mathrm{h}_{\text {max }}\right)$ <br> band 2: $80-50 \%$ of $h_{\text {max }}$ <br> band 3: $50-0 \%$ of $h_{\max }$ | Shannon index calculation for the proportion of tree species in different stand layers | Pretzsch 1996 |

Additionally the standard deviation of dbh was calculated as this measure has been shown to be a strong index for horizontal stand structure by Neumann and Starlinger (2001).

The different indices are described in detail by Anonymus (2004) and Fischer and Pommerening (2003).

In the field a list of simple estimates was recorded (Table 2), which are also described in detail by Anonymus (2004) and Fischer and Pommerening (2003).

Tab. 2: List of simple estimates

| Parameter | Estimation/Classes |
| :---: | :---: |
| Tree species composition | estimated list of main tree species with percentage cover in $10 \%$ steps; list of all additional tree species occurring without percentage cover |
| Number of tree layers > 5m | - one layer <br> - two layers (each min of $10 \%$ coverage) <br> - multilayered (each min of $10 \%$ coverage) <br> - irregular |
| Type of tree species mixture | - monoculture ( $>90 \%$ tree cover consists of main tree species) <br> - single tree wise mixture <br> - group wise mixture <br> - mixture by layers <br> - irregular, none of the above |
| Canopy closure | percentage coverage of tree layer > 5 m (5\% steps) |
| Ancient forest site | - forested since > 300 years <br> - forested since > 200 years <br> - forested since > 100 years <br> - afforested in the past 100 years |
| Intensity of forest management | - no sign of management, natural development <br> - signs of past management, abandoned to natural development <br> - managed |
| Management type of forest | - high forest <br> - coppice without standards <br> - coppice with standards <br> - plantation |
| Management method | - clear cut <br> - clear cut with reservoirs <br> - selective cut |

Additionally stem number and basal area per ha were calculated for all trees $\geq 5 \mathrm{~cm}$ dbh. Volume (either total volume over 5 or 7 cm diameter or - in case of coniferous trees - stem wood) was calculated if the determination of dbh-height relations was possible.

Table 3 summarizes the scale (from single tree to tree stand) and the kind of expected results of the different indices selected.

Tab. 3: Scale and kind of results per attribute and index.

| Unit of inventory | Inventoried (or derived) attribute | Computed index | Result concerning |
| :---: | :---: | :---: | :---: |
| single tree | Dbh | standard deviation | horizontal structure |
|  | tree species | Shannon index, Simpson Index | tree species diversity |
|  | Height + tree species | species profile index | combined vertical (height bands) and tree species diversity |
|  | Coordinates | Clark Evans index | horizontal structure |
| group of trees | angle between central tree and neighbours | contagion index | small scale horizontal structure |
|  | species of neighbours compared to central tree | Mingling index | small scale species diversity |
|  | diameter of $1^{\text {st }}$ neighbour compared to central tree | diameter differentiation | small scale diameter differentiation |
| stand | simple estimate of tree species composition | no computation | tree species composition and diversity |
|  | simple estimate of the number of tree layers |  | vertical structure |
|  | simple estimate of the type of tree species mixture |  | spatial tree species diversity |
|  | simple estimate of canopy closure |  | density |
|  | dbh, height | Stem number, basal area and volume per ha | density; standard measures for forests |

## Data submitted

The submitted data allowed for the computation of almost all indices. Exceptions are documented in Annex 3. Simple estimates were submitted for 82 plots.

## 3 Field assessments

### 3.1 Plot configuration

## Approach

The ForestBIOTA plot for stand structure assessments must be entirely contained within the Level II plot. It must always be continuous and of 0.25 ha size. A division to disjunctive parts is not foressen. The plot is centered as far as possible in correspondence with the geometric center of the Level II plot. The plot should be shaped as far as possible as a square, with a side length of 50 m . Otherwise, it may be shaped as a moderate rectangle, preferably with a minimum width of 40 m (or a maximum length of 62.5 m ). One side of the plot is oriented to the magnetic North if possible.

## Delivered data

The countries guaranteed that the standard plot size of $2,500 \mathrm{~m}^{2}$ has been observed. However, length of the plot axis and information on plot orientation have not been reported. Visualisation of spatial tree distribution (s. Fig. 2) revealed that the majority of plots are shaped in accordance with the above agreements. A deviation from the standard size was reported for the Greek plots $209\left(2,624 \mathrm{~m}^{2}\right), 309\left(2,733 \mathrm{~m}^{2}\right)$ and $409\left(2,990 \mathrm{~m}^{2}\right)$ and the Italian plot $15\left(2,100 \mathrm{~m}^{2}\right)$.

Some countries submitted data for trees, which are not located within the ForstBIOTA plot. These trees were marked in the dataset and left aside for computation.
From Switzerland data on two types of plots were delivered: a) plots, where all trees $\geq 5$ cm dbh have been assessed, and b) plots, where only trees $\geq 12 \mathrm{~cm}$ have been measured. The latter were designated by Switzerland as ForestBIOTA plots, and subsequently dead wood inventories were carried out there. As meeting the criterion of a dbh limit of 5 cm is vital for comparable data analysis in the field of stand structure the Swiss ForestBIOTA plot could not be used for computation. Instead, the first plot type was selected.

### 3.2 Inventoried parameters

## Approach

The list of necessary inventory parameters was derived from the list of calculated indices and growth and yield data. Therefore following parameters of the stand $\geq 5 \mathrm{~cm}$ dbh had to be assessed (s. Tab. 3):

- Dbh [cm; full survey]
- Tree species [Botanical name; full survey]
- Height [m; sample or full survey]
- Coordinates [preferable: full survey of $x$ - and $y$ - or polar coordinates; in stands with more than 1.000 trees per ha systematic samples of structural groups of four were foreseen s. chapter 4]

The assessment methodology is documented in Anonymus (2004).

## Data submitted

Data were submitted for 95 plots from 11 countries. Data quality was high and the datasets were almost complete. Necessary corrections as well as completions are documented in Annex 2.
As a consequence of a negative pilot study (s. chapter 4) systematic samples of structural groups of four have not been assessed in the field.
Only for 6 plots tree coordinates were missing (all French plots and plot nr. 603 in
Germany). Height measurements were not available for 13 plots (all French plots, 7 German plots and one Ukrainian plot).

## 4 Simulation study: sampling of structural group of four

The assessment of tree coordinates is time-consuming. Prior to developing the assessment methodology it therefore had to be decided whether the sampling of structual groups of four would be advisable. A simulation study was therefore conducted based on 23 Level II plots from which a full survey of tree coordinates was available.

The computation was carried out in cooperation with K. Staupendahl from the Institute of Forest Inventory and Growth of the University of Göttingen.
Sampling in a regular grid with sample size of 10, 20, 30, 40 and 50 (standard design) or $4,8,12,16,20$ resp. (clustered design, 4 groups per sample, s. Hui and Albert 2004) was simulated using the software POISSSIM ${ }^{\text {Tw }}$ (Zitat der Quelle?). 500 replications per sample size and plot with randomized grid starting point and randomized angle were computed. Relative bias and relative root mean squared error (rRMSE) were calculated for the different plots and samples sizes (s. formula 1 and 2). A negative exponential function was fitted to analyse the relationship between rRMSE and sample size (s. formula 3).

$$
\begin{equation*}
r B I A S=\frac{B}{\mu}=\frac{\sum_{i=1}^{n}\left(\overline{x_{i}}-\mu\right) / n}{\mu} \tag{1}
\end{equation*}
$$

with
rBIAS = relative bias
$\bar{x}_{i}=$ sample mean of structural group of four in repetition i
$\mathrm{n}=$ number of repetitions
$\mu=$ true mean of the population
$r$ RMSE $=\frac{\sqrt{s_{x}^{2}+B^{2}}}{\mu}$
with
rRMSE = relative root mean squared error
$\mathrm{s}=$ standard deviation
B = bias
$\mu=$ true mean of the population

$$
\begin{equation*}
r R M S E=a \cdot n S A M P L E S^{-b} \tag{3}
\end{equation*}
$$

with
rRMSE = relative root mean squared error
a, b = parameters
nSAMPLES = number of samples
Results of the simulation study reveal a considerable bias of sampling structural group of four, especially in respect to species mingling (Fig. 1). This problem is well-known (see e. g. Hui and Albert 2004), but yet unsolved. Calculation of necessary sample size shows that the clustered design is less susceptible to bias (Tab. 4). Anyhow, the necessary sample size often is so high that a full survey would be more efficient on the comparatively small Level Il plots.

Tab. 4: Necessary sample size of structural groups of four to fall below a rRMSE of 5 or $10 \%$. Two different sample designs are distinguished: standard design with single groups and clustered design with 4 groups respectively (for details s. Hui and Albert 2004).

| Rel. RMSE \% | Parameter | N Samples |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Min. | Max. | Mean | UCL $95 \%$ |
| Standard design |  |  |  |  |  |
| 5 | Contagion | 55 | 732.867 | 36.294 | 91.116 |
|  | Mingling | 60 | 2.031.256 | 146.248 | 336.768 |
|  | DBH differentiation | 82 | 2.403 | 286 | 458 |
| 10 | Contagion | 12 | 2.956 | 193 | 418 |
|  | Mingling | 16 | 147.903 | 8.754 | 22.177 |
|  | DBH differentiation | 23 | 233 | 53 | 68 |
| Clustered design |  |  |  |  |  |
| 5 | Contagion | 10 | 429 | 42 | 73 |
|  | Mingling | 25 | 55.457 | 4.376 | 9.441 |
|  | DBH differentiation | 31 | 247 | 66 | 82 |
| 10 | Contagion | 3 | 14 | 5 | 6 |
|  | Mingling | 6 | 7.261 | 670 | 1.352 |
|  | DBH differentiation | 8 | 42 | 18 | 20 |

Fig. 1: Relationship between rRMSE and sample size for species mingling based on calculations for 23 Level Il plots with full survey of tree coordinates. In many cases an error limit of 10 or $5 \%$ can only be achieved with an extraordinarily high sample size.

On the basis of these results it was recommended to sample structural groups of four only in plots with high stem numbers of $>1,000$ trees per ha.

## 5 Data processing

The Programme Coordinating Centre of ICP Forests, hosted by the Federal Researech Centre for Forestry and Forest Products in Hamburg, Germany created a database in MS Access ${ }^{\text {TM }}$. Computations were carried out under SAS 8.2 ${ }^{\text {TM }}$. Source codes were written for data import and check of data quality and completeness. After correcting and completing, the data were analysed in following steps:

- Visualising tree positions and dbh in plot maps
- Detecting border trees
- Calculating spatially explicit indices for all trees $\geq 5 \mathrm{~cm}$ dbh. Border trees were only accepted as neighbors but not as central tree of a structural group or pair.
- Calculating indices without spatial relation
- Constructing height curves, if necessary
- Calculating tree and stand volume

## 6 Results

### 6.1 Visualization of tree distribution and detection of border trees

Under SAS $8.2^{\text {TM }}$ a source code was written for the scalable display of the spatial tree distribution at ForestBIOTA plots. These tree distribution maps were used to check plausibility of plot size, spatial pattern and designation of border trees.
Fig. 2 shows an example of the different tree groups, which had to be distinguished prior to data analysis: trees inside the plot (green = accepted as central trees), border trees (red = only accepted as neighbours) and trees outside the plot (black = left aside for computation).

Spatial tree distribution Level II plot 1202, country 4

Fig. 2: Example of a tree distribution map showing trees inside the plot, border trees and trees outside the plot.

Border trees were detected as follows:

1. Each tree was defined as origin of a cartesian coordinate system and the $x$ - and $y$ coordinates of all other trees in the frame of this system were calculated
2. If no trees could be found in two adjacent $45^{\circ}$ sectors around the respective tree it was defined as border tree
As could be stated by visual check the routine worked reliable without exception.
The visual check revealed that the majority of plots is shaped rectangular and plot size did not deviate from the required $2500 \mathrm{~m}^{2}$ except for minor deviations from the standard size in 4 cases (s. chapter 3.1).
Dbh visualisation revealed that circumference instead of diameter data had been submitted in three cases. Data were recalculated respectively.

### 6.2 Calculated indices

Indices characterizing stand structure were calculated according to Tab. 1. Some main results related to forest types are presented below (s. Fig. 3-9).

### 6.2.1 Tree species diversity

Tree species diversity is described by number of tree species (Fig. 3), Shannon index (Fig. 4) and mean mingling (Fig. 5).

Results are shown only for those plots, where calculation of all indices was possible and forest type information was available ( $\mathrm{n}=84$ ). Forest types have been condensed to 8 main types in order to ensure sufficient plots per type. All other types were summarized to the group 'Others'.

No obvious and general relationship between forest type and tree spcies diversity can be detected. Nevertheless high diversity values seem to be associated with plots of the Mesoeutrophic Oak Forests and Mountainous Mixed Beech Forests. An in-depth analysis is necessary to assure or reject possible relationships.

### 6.2.2 Spatial tree distribution

Spatial tree distribution is described by the Clark and Evans index (Fig 6) and the mean contagion (Fig. 7).

The visual comparison reveals that results of the two indices seem to be rather comparable. Clumped tree distributions indicated by a Clark and Evans value below 1.0 and a mean contagion above 0.5 occur mainly on plots of Mediterranean Broadleaved forests while random to regular spatial patterns seem to be typical for the plots classified as Taiga Woodlands and Coniferous Plantations. However, the range of contagion values is rather small. Thus differences between plots are not as prominent as compared to the Clark Evans Index.

### 6.2.3 Differentiation

Diameter differentaition is described by the mean diameter differentiation (Fig. 8) and the standard deviation of dbh (Fig. 9).

Both paramters indicate that especially the plots in Beech Forests and Fir/Spruce Woodlands are highly differentiated. The results of both indices are rather compatible.

Fig. 3: Number of tree species per plot (country-plot nr.) and forest type in ascending order.

Fig. 5: Values of mean mingling per plot (country-plot nr.) and forest type in ascending order.

Fig. 6: Values of the Clark and Evans index per plot (country-plot nr.) and forest type in ascending order.

Fig. 7: Values of the mean contagion per plot (country-plot nr.) and forest type in ascending order.

Fig. 8: Values of the mean diamter differentiation per plot (country-plot nr.) and forest type in ascending order.

Fig. 9: Standard deviation of dbh per plot (country-plot nr.) and forest type in ascending order.

### 6.3 Significance of simple estimates

Simple estimates can be assessed easier than the attributes necessary to derive calculated indices. They might therefore be considered an alternative.

As can be shown by non-parametric test statistics calculated indices differ significantly between classes of simple estimates (Tab. 5). Thus simple estimates can reflect differences in stand structure to a certain degree. Nevertheless it is questionable whether they are sufficiently exact to substitute calculated indices.
Furthermore comparison between calculated indices and simple estimates is limited because they do not correspond directly to one another (e. g. Type of species mixture estimates species diversity as well as spatial distribution)
Another aspect is that that classes of simple estimates had to be condensed in order to increase and balance sample size: concerning the parameter 'number of tree layers' the classes 'multilayered' and 'irregular' were fused, concerning 'type of tree species mixture' in contrast to 'monocultures' ( 50 samples) all other 'mixed stands' were fused to one class. This shows the difficulties of the statistical analysis of simple estimates in case that plots are selected without pre-stratification. Simple estimates could well be used as stratification criterion for plot selection in order to gain a balanced dataset.

Tab. 5: Results of Kruskal-Wallis tests on significant differences between classes of simple estimates in respect of calculated indices (propability of a higher Chi-square value, n. s. = not significant). Simple estimates had to be condensed in order to increase and balance sample size per class (s. text).

| Calculated index | Simple estimate |  |
| :--- | :---: | :---: |
|  | Number tree <br> layers | Type species <br> mixture |
| Clark Evans index | $<0.01$ | $<0.05$ |
| Contagion index | $<0.05$ | n. s. |
| Mingling index | n. s. | n. s. |
| Diameter differentiation | $<0.001$ | $<0.001$ |
| Standard deviation dbh | $<0.01$ | $<0.001$ |
| Shannon index (stem number) | n. s. | $<0.001$ |
| Evenness (stem number) | $<0.01$ | $<0.001$ |
| Shannon index (basal area) | n. s. | $<0.001$ |
| Evenness (basal area) | $<0.01$ | $<0.001$ |
| Simpson index (stem number) | n. s. | $<0.001$ |
| Simpson index (basal area) | n. s. | $<0.001$ |
| Species profile index | n. s. | $<0.001$ |
| Evenness species profile index | n. s. | $<0.001$ |

## 6. 4 Calculation of volume

Exact volume calculation requires dbh and height values for all trees on a Level II plot. These values are input parameters for volume functions. For 82 out of 95 plots sampled height values were available. Dbh-height relations were derived on the basis of formula 4 (Petterson-function s. Kramer and Aksa 1995). Subsequently volume per ha was computed by the PCC and the expert on the basis of volume functions specific for country and tree species.

$$
\begin{equation*}
h=1.3+\left(\frac{d b h}{a+b \cdot d b h}\right)^{3} \tag{4}
\end{equation*}
$$

where
$\mathrm{h}=$ tree height [ m ]
$\mathrm{dbh}=$ diameter at breast height $[\mathrm{cm}]$
$a, b=$ parameters

## 7 Recommendations

Based on the outcomes of the data analysis the following recommendations can be given:
In order to guarantee comparable results plot shape and not only plot size should be harmonized. Irregular or transect-like shape increases border effects and reduces the proportion of central trees (s. chapter 6.1). It must therefore be recommended to observe the plot configuration rules (s. chapter 3.1) strictly.

On a first glance the calculated indices show comparable results. Nevertheless reliable conclusions about correlations between indices as well as their validity can only be drawn after in-depth data analysis. Considering the variability between plots, almost all indices reflect differences of stand structure seemingly well. An exception might be the mean contagion. After these first evaluations, the calculated indices fulfilled the requirements with respect to sensitivity, comparability and validity.

The inventory of the attributes dbh, tree species, height and coordinates allows for a multitude of subsequent calculations. Therefore the applied inventory design can be recommended without restrictions.

The full survey of coordinates is recommended because of the high potential of spatially explicit indices for data analysis. In addition, coordinates help to re-identify trees in the course of repeated surveys.

Full survey of tree heights might on the one hand be too labour intensive. On the other hand it is a prerequisite for exact results concerning vertical structure. As an alternative, trees can be assigned to height bands (s. Tab. 1). In any case, height values are needed for volume calculations. A final recommendation concerning the number of necessary height measurements can therefore not be given.

Concerning simple estimates the results of future in-depth data analysis must be taken in consideration. Yet no recommendations can be given. However it becomes apparent that
they can not serve as an equivalent substitute of calculated indices., Estimating height bands might Probably be an alternative to the full survey of tree heights.

## Annex 2: Problems and data correction

| Country | Plotnr | Problem | Correction/Solution |
| :---: | :---: | :---: | :---: |
| 1 | 36 | Coordinates missing; height values missing | No calculation of spatial indices and volume |
| 1 | 37 | Coordinates missing; height values missing | No calculation of spatial indices and volume |
| 1 | 42 | Coordinates missing; height values missing | No calculation of spatial indices and volume |
| 1 | 53 | Coordinates missing; height values missing | No calculation of spatial indices and volume |
| 1 | 76 | Coordinates missing; height values missing | No calculation of spatial indices and volume |
| 3 | 106 | Extreme value coordinates treenr 22; | New coordinate $\mathrm{x}=\mathrm{x}-700, \mathrm{y}=\mathrm{y}-330$ |
| 3 | 175 | Tree-Nr. 596 without coordinates and species classification | Deleted |
| 3 | 1040 | treenr 101 without species classification; 10 trees with species code $=0$ | species treenr $101=71$; species code 0 left unchanged |
| 3 | 2084 |  |  |
| 3 | 2085 |  |  |
| 4 | 101 |  |  |
| 4 | 301 | Height values missing | No calculation of volume |
| 4 | 305 |  |  |
| 4 | 502 | Tree Nr. 81: dbh missing | Average dbh of species 51 inserted |
| 4 | 503 |  |  |
| 4 | 508 |  |  |
| 4 | 603 | Coordinates missing; height values missing | No calculation of spatial indices and volume |
| 4 | 606 | 3 dbh missing; height values missing | Average dbh inserted; no calculation of volume |
| 4 | 608 | Height values missing | No calculation of volume |
| 4 | 703 |  |  |
| 4 | 704 |  |  |
| 4 | 706 |  |  |
| 4 | 707 | Height values missing | No calculation of volume |
| 4 | 903 |  |  |
| 4 | 919 |  |  |
| 4 | 1202 |  |  |
| 4 | 1203 |  |  |
| 4 | 1205 |  |  |
| 4 | 1401 | Mingled inside and outside trees; height values missing | In accordance with PCC: correct classification as 1) trees outside the plot or 2) trees thinned (are deleted); no calculation of volume |
| 4 | 1402 | Height values missing | No calculation of volume |
| 5 | 1 | Management type = coppice with standards: choice of volume equations unclear | Volume equations coppice applied |
| 5 | 3 | Management type = coppice with standards: choice of volume equations unclear | Volume equations coppice applied |
| 5 | 8 |  |  |
| 5 | 10 |  |  |
| 5 | 14 |  |  |
| 5 | 15 | Plot size $2100 \mathrm{~m}^{2}$ | Deviation from standard size acceptable |
| 5 | 16 |  |  |
| 5 | 17 | Management type = coppice with standards: choice of volume equations unclear | Volume equations coppice applied |
| 5 | 21 | Management type = coppice with standards: choice of volume equations unclear | Volume equations coppice applied |
| 5 | 22 | y-coordinate of treenr 196 und 197 to high | $Y=y / 10$ |
| 5 | 25 |  |  |
| 5 | 27 | Management type = coppice with standards: choice of volume equations unclear | Volume equations coppice applied |
| 8 | 51 | Height values without treenr. | Separate calculation of height curves |
| 8 | 64 | Height values without treenr | Separate calculation of height curves |

## Annex 2: Problems and data correction (continued)

| Country | Plotnr | Problem | Correction/Solution |
| :---: | :---: | :---: | :---: |
| 8 | 74 | Height values without tree nr; treenr 4 and 5 without species classification | Separate calculation of height curves; species treenr 4 and 5 $=20$ |
| 8 | 95 | Height values without tree nr | Separate calculation of height curves |
| 9 | 209 |  |  |
| 9 | 309 | Plot too large | Identification of trees inside the FB plot ; exact plot size communicated by country representative |
| 9 | 409 |  |  |
| 11 | 5 | Assymetric plot shape | Plot size of $2500 \mathrm{~m}^{2}$ assured by country |
| 11 | 6 |  |  |
| 11 | 10 |  |  |
| 11 | 11 |  |  |
| 11 | 15 | Assymetric plot shape | Plot size of $2500 \mathrm{~m}^{2}$ assured by country |
| 11 | 22 |  |  |
| 11 | 25 |  |  |
| 11 | 26 |  |  |
| 11 | 30 |  |  |
| 11 | 33 | Plot too small | Plot size of $2500 \mathrm{~m}^{2}$ assured by country |
| 11 | 37 |  |  |
| 11 | 102 |  |  |
| 15 | 2 | Plot too large | Identification of trees inside the FB plot |
| 15 | 3 | Plot too large | Identification of trees inside the FB plot |
| 15 | 5 | Plot too large | Identification of trees inside the FB plot |
| 15 | 6 | Plot too large; some trees obviously outside the plot area | Identification of trees inside the FB plot |
| 15 | 10 | Plot too large | Identification of trees inside the FB plot |
| 15 | 11 | Plot too large | Identification of trees inside the FB plot |
| 15 | 12 | Plot too large | Identification of trees inside the FB plot |
| 15 | 13 | Plot too large | Identification of trees inside the FB plot |
| 18 | 201 | Some DBH values > 100 cm ; volume and basal area too high | Circumference delivered instead of dbh; values recalculated |
| 18 | 206 | Some DBH values > 100 cm ; 1 dbh missing; volume and basal area too high | Circumference delivered instead of dbh; values recalculated; Average dbh inserted for missing value |
| 18 | 207 | Some DBH values > 100 cm ; volume and basal area too high; treenr 209 without species classification | Circumference delivered instead of dbh; values recalculated; species = 118 |
| 20 | 1 | Plot too large | Identification of trees inside the FB plot |
| 20 | 2 | Plot too large | Trees classified as 1) inside a plot where all trees with dbh $\geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |
| 20 | 3 | Plot too large | Trees classified as 1 ) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |
| 20 | 4 | Plot too large | Trees classified as 1) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |
| 20 | 5 | Plot too large | Trees classified as 1 ) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |
| 20 | 6 | Plot too large | Trees classified as 1 ) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |
| 20 | 7 | Plot too large; two separated plots | Trees classified as 1 ) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |
| 20 | 8 | Plot too large | Trees classified as 1 ) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |
| 20 | 9 | Plot too large | Trees classified as 1) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |
| 20 | 10 | Plot too large; 4 trees without DBH | Trees classified as 1 ) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1 ); avergage dbh inserted |
| 20 | 11 | Plot too large | Trees classified as 1 ) inside a plot where all trees with $\mathrm{dbh} \geq 5 \mathrm{~cm}$ were measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); calculation of structural indices only for 1) |

## Annex 2: Problems and data correction (continued)

| Country | Plotnr | Problem | Correction/Solution |
| :--- | :--- | :--- | :--- |
| 20 | 12 | Plot too large | Trees classified as 1) inside a plot where all trees with dbh $\geq 5 \mathrm{~cm}$ were <br> measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); <br> calculation of structural indices only for 1) |
| 20 | 13 | Plot too large | Trees classified as 1) inside a plot where all trees with dbh $\geq 5 \mathrm{~cm}$ were <br> measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); <br> calculation of structural indices only for 1) |
| 20 | 14 | Plot too large; height values to <br> low? Some very high dbh <br> values | Trees classified as 1) inside a plot where all trees with dbh $\geq 5 \mathrm{~cm}$ were <br> measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); <br> calculation of structural indices only for 1); DBH and height values are <br> correct |
| 20 | 15 | Plot too large | Trees classified as 1) inside a plot where all trees with dbh $\geq 5 \mathrm{~cm}$ were <br> measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); <br> calculation of structural indices only for 1) |
| 20 | 16 | Plot too large; 2 separated <br> plots | Trees classified as 1) inside a plot where all trees with dbh $\geq 5 \mathrm{~cm}$ were <br> measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); <br> calculation of structural indices only for 1) |
| 20 | 17 | Plot too large | Trees classified as 1) inside a plot where all trees with dbh $\geq 5 \mathrm{~cm}$ were <br> measured and 2) trees inside the FB plot (measured $\geq 12 \mathrm{~cm}$ ); <br> calculation of structural indices only for 1) |
| 24 | 541 | 2015 | 2171 |
| 24 | 1 | 4 trees outside the FB plot |  |
| 24 | (Nr.: 102, 105, 106, 107); |  |  |
| height values missing |  |  |  |
